[1] alkenes is often oato as a synonym of olephine, i.e. any hydrocarbon or more double bonds [2] two general types of monoalkenes arteminal and internal. Also called α -olefines, alken terminal are more useful. However, the International Union of Pure and Applied Chemistry (IUPAC) recommends using the alkene name only for acyclic hydrocarbons with two or more double bonds: cycloalkenes, cycloalkadiene, etc. for cyclic ones; and olefins for the cyclical class [3][4][5] Acyclic alkids, with only one double bond and no other functional group (also known as monone) form a homologation series of hydrocarbons with the general formula $CnH2n$ with n to be 2 or more (which is two hydrogen less than the alcan correspondent). When n is four or more isomers are possible, distinct from the position and conformation of the double bond. Alkenes are non-polar compounds colourless, a bit similar to alkanes but more reactive. The first members of the series are gases or liquids at room temperature. The simplest alchene, ethylene ($C2H4$) (or ethene in the IUPAC nomenclature) is the organic compound produced on a large scale industrially. [6] The aromatic compounds are often drawn as cyclical alkenes, however their structure and their properties are sufficiently distinct that they are not classified as alkenes or olefins. [4] Hydrocarbons with two double overlapping bonds ($C=C=C$) are called dienes, the simplest such compound is called alenes, and those with three or more overlapping bonds ($C=C=C=C=C=C=C=C$, etc.) are called cumulans. Some authors[who?] do not consider the fanes and cumulanes to be alkenes. Structural hypermarkets Alkenes with four or more carbon atoms can form different structural isomers. Most alche are also cycloalkene isomers. The structural isomers of acyclic alkenes with only one double bond follow:[7]-[24]: ethylene C₂H₄; allyl propylene C₄H₆; 3 isomers: propene, α -methylpropene, β -methylpropene; 1-butene, 2-butene,
